

By Johanna Broupi

Telehealth is the delivery of health-related services and information with the help of telecommunication technologies. Telehealth could be as simple as a discussion on the telephone or as sophisticated as doing robotic surgery.

At first, it was used to describe administrative or educational functions related to telemedicine. Today telehealth provides a lot of technology solutions. For example, doctors use email to communicate with patients, order drug prescriptions and provide other health services. One of the most important increases in usage of telehealth is the home monitoring of conditions of vulnerable patients, such as the people who have serious problems of health and live in islands and remote villages without having access to health-services, which they need and telehealth gives solutions to their problems.

So it minimizes distances with the help of technology and the future will be better and health will be cheaper and faster for everyone.
